Bat Testing for Suspect and Confirmed Exposures

Persons with a suspect or confirmed bat exposure can have the bat tested at no cost at the WA DOH Public Health Lab to determine if the bat is rabid and rabies PEP is necessary. Prior authorization by the health department is necessary before the bat can be submitted. The Chelan-Douglas Health District will package and submit the bat for testing. Please call CDHD for additional information (509)886-6400.

**Guidance on testing and PEP if bat is available:**

In any exposure or potential exposure situation, the bat in question should be submitted for testing. It is always preferable to test the bat because a negative result will rule-out exposure to rabies.

- If positive, give PEP.
- If negative, no need for PEP; discontinue PEP if already started.

**Guidance on PEP if bat is not available to test:**

- Person with a known bat bite, scratch or mucous membrane exposure → Recommend PEP
- Person has other type of direct contact with a bat (e.g., bat lands on person, bat flies into person) → Recommend PEP unless the person is reasonably certain a bite, scratch, or mucous membrane exposure did not occur.
- For unattended children, is the child old enough to be a reliable witness about whether contact occurred?

**Bat found in the room** with a person who might be unaware that a bite or direct contact occurred, e.g., a person wakes up to find a bat in the room OR a reliable person witnesses a bat in the room with a previously unattended child, a person with impaired level of consciousness (i.e., underlying disease, mental disability, intoxication, etc.) → Generally recommend PEP

Other considerations for a bat found in a room:

- For unattended children found with a bat in the room, is the child old enough to be a reliable witness about whether any contact occurred?
- For others sleeping in adjacent or nearby rooms with doors that were open to room where bat found, PEP is not routinely recommended though may be appropriate in some circumstances. Consider how the bat likely entered the home, where it was found in proximity to rooms, open window, chimney, etc.

**Recent Washington trends:** Of bats tested in Washington 5-10% are identified as rabid, though this represents a skewed population of sick or injured bats. In the wild, we estimate less than 1% of bats are actually rabid. Since 1987, only four rabid domestic, terrestrial animals were identified, two with bat variant virus.
Fifteen rabid bats were identified during 2014.
# Washington State Guidelines for Human Rabies Prevention

- **All suspected rabies exposures (to people)** must be immediately reported to the local health jurisdiction (LHJ) per WAC 246-101. This includes reporting of all persons to whom rabies post-exposure prophylaxis (PEP) is administered.
- **Consultations and animal testing** are available from the LHJ. Healthcare providers are encouraged to consult LHJs prior to initiating PEP.
- **Rabies exposures include** bites, scratches, and fresh wounds or mucous membranes contaminated with a mammal’s saliva or neural tissue. Touching animal fur, blood, urine, or feces is not a rabies exposure. Non-mammals, e.g., birds and reptiles, do not get rabies. Bat exposures* deserve special consideration.

## Risk Categories

<table>
<thead>

Washington State Guidelines for Human Rabies Prevention

* Rabid-acting: Rabies virus causes an acute, rapidly progressive encephalitis. Observing unusual behavior or unhealthy appearance is a proxy to identify potentially rabid animals. Behavior changes and neurologic signs exhibited are variable based on species and stage of disease progression. In terrestrial mammals, suggestive signs include being unusually withdrawn, stuporous or agitated; acting inappropriately aggressive or attempting to bite; approaching people (wild animals only); attacking inanimate objects; making abnormal vocalizations; stumbling or appearing weak; displaying muscle tremors, seizures, or difficulty swallowing; appearing afraid of water; salivating profusely (foaming at the mouth); and staring blankly or appearing to be blind. Livestock may also display head-pressing, circling, depression, drooping head or ears, or constant bellowing, or may isolate themselves from herd mates.

† Bats: May assume exposure when a bat is found in a room with a person who cannot say that exposure did not occur (e.g., unattended infant or child, intoxicated adult, sleeping person). Bat bites may not leave visible marks. See detailed bat exposure assessment document for additional information on exposure assessments related to bats.

§ Observations: Local county policy may differ as to whether dog/cat/ferret (D/C/F) observation should be done in home or with animal control. If D/C/F becomes ill or dies during observation, a veterinarian should be consulted to evaluate for rabies and the LHJ should be notified immediately.

^ Notifying LHJ: In general, low risk bites/exposures from dogs, cats, and ferrets in Washington and rodents, rabbits, opossum, and livestock are not reportable to the LHJ. However if PEP is given or animal shows signs of rabies, then exposure must be reported to the LHJ.

provoked exposures: May include invasion of an animal’s territory (potentially even running by a dog), assisting an injured animal, startling or trying to capture an animal, coming between an animal and its young, taking food away from an animal, acting aggressively toward an animal, breaking up a fight between animals, or trying to touch, pet, or feed an unfamiliar animal. Provocation must be considered from the animal’s perspective. An exposure is considered “unprovoked” if these behaviors are absent; for example, an animal suddenly appears or charges and bites a person who was not in any way interacting with the animal or its young.

Legal reporting requirements in Washington State regulation (WAC 246-101-101 and -301)
- All healthcare providers, healthcare facilities, and veterinarians are required to immediately notify the local health jurisdiction (LHJ) regarding suspected rabies exposures, including: (1) “Animal bites (when human exposure to rabies is suspected),” and (2) “Rabies, suspected human exposure (suspected human rabies exposure due to a bite from or other exposure to an animal that is suspected to be rabid)”
- The algorithm is intended to be a guide in determining whether an exposure to rabies should be suspected and whether reporting to the LHJ is necessary.

Washington State rabies facts
- Bats are currently the only known reservoir for rabies in Washington State.
  - Rabies is not known to be endemic in raccoons, skunks, foxes, or other wild carnivores in this state; however surveillance for rabies in wild carnivores is minimal in Washington.
  - Rarely, other animals are bitten by bats and may become rabid in Washington State; examples since 1988 include horse, llama, and cat.
- Animals incubating or infected with rabies could be accidentally imported into Washington State.
  - Risk differs elsewhere in the world (e.g., raccoon rabies in the east coast, skunk rabies in central states, dog rabies in Asia and Africa, etc.).

Criteria for assessing risk of rabies exposure
- Consider the following: (1) animal type and health/behavior (see rabid-acting); (2) geographic location of exposure; (3) animal vaccination status; (4) circumstances of exposure (provoked vs. unprovoked); (5) likelihood the animal could have been exposed to another rabid animal (outdoor vs. indoor animal; travel/import history of animal; feral/stray vs. pet).
- If you are unsure, consultations are available from your LHJ. If unable to reach LHJ, call DOH Communicable Disease Epidemiology (see below).

Wound care
- Wound cleansing is important in rabies prevention. In animal studies, thorough wound cleansing alone has been shown to reduce the likelihood of rabies.
